

Website Conversion A/B Test

A data-driven case study on redesigning the website experience to improve customer conversion

Executive Summary

The company tested a new website design against the current version to see whether it improves the rate at which visitors convert into customers. The new design increased conversions from **5.4% to 14.1%** — nearly a **3x improvement** — based on a controlled test of 5,000 users. This lift held true across every device type and every UK region tested, giving high confidence that the result reflects a genuine improvement rather than chance.

Recommendation: Roll out the new website design to all users.

The Business Question

The UX team built a redesigned version of the website, believing it would guide visitors to convert more often. Before rolling it out to everyone, the business needed a clear, evidence-based answer to one question: **does the new design actually perform better, or could any observed difference just be random variation?** To find out, visitors were randomly split into two groups — one saw the current site (Group A), the other saw the new design (Group B) — and their behavior was tracked and compared.

Finding 1: The New Design Significantly Outperforms the Current One

Overall Conversion Rate: New vs Current Version

Conversion rate comparison across 5,000 tested users

Visitors who saw the new design converted at nearly 3 times the rate of those who saw the current site. This gap is large enough, and consistent enough across the full sample, that it is extremely unlikely to be due to chance — statistical testing confirms this difference is real with over 99.9% confidence.

Finding 2: The Improvement Is Not Explained by Device or Location

A natural follow-up question: did the new design simply happen to reach more mobile users, or users in a region that converts better anyway? The data rules this out. Both test groups were evenly split across Desktop/Mobile and all four UK regions, and the new design outperformed the old one in **every single device type and every single region** — not just on average.

Conversion Rate by Device

Conversion rate by device type

Finding 3: Visitors Didn't Browse Differently — They Just Converted More

Interestingly, the two groups spent nearly identical time on the site and viewed a similar number of pages. This tells us the new design didn't work by making people browse longer or explore more — it worked by making the path to conversion clearer or more compelling. That's a useful insight for the design team going forward: the win came from friction reduction, not engagement.

How Confident Can We Be In This Result?

Two checks were run to make sure this conclusion is trustworthy before recommending a company-wide rollout:

- **Sample size:** The test used far more users than the minimum needed to detect a difference this size reliably, so the result is not a fluke of a small sample.
- **Consistency:** The improvement held up across every segment examined (device, region) rather than being driven by one group, which rules out a misleading test setup.

Based on the full range of likely outcomes, the true improvement is estimated to fall between roughly **7 and 10 percentage points** — even in the more conservative case, this is a meaningful and worthwhile gain.

Recommendation

Ship the new website design to all users. The improvement is large, statistically reliable, and consistent across customer segments. Before full rollout, use the conservative end of the estimated improvement (7 percentage points) to project the revenue impact and build the business case.

Analysis based on a controlled test of 5,000 website visitors, evenly and randomly split between the current and new website designs.
